Divide and Conquer

Divide and Conquer for finding Counterfeit coin (exactly one coin):

```
Algorithm CounterfeitCoin(Bunch, numberofcoins)
{
    if (numberofcoins = 2)
    {
        weigh the two coins;
        if one of them weighs less that is counterfeit coin;
    }
    else
    {
            Divide Bunch into two halves Bunch1 and Bunch2;
            if Bunch1 weighs less than Bunch 2, call CounterfeitCoin(Bunch1, numberofcoins / 2);
            else, call CounterfeitCoin(Bunch2, numberofcoins / 2);
        }
}
```

Finding Largest with Divide and Conquer:

```
Algorithm DandCLargest (a,k, j)
{
    if (k = j)
        Return a[n];
    else
    {
        mid := (k + j) /2;
        x1= DandCLargest (a,k,mid);
        x2= DandCLargest (a,mid+1,j);
        if (x1 > x2)
            Return x1;
        else
            Return x2;
    }
}

First Call for Recursion:
DandCLargest (a,1,n);
```

Divide and Conquer algorithm design works on the principle of dividing the given problem into smaller sub problems which are similar to the original problem. The sub problems are ideally of the same size.

The Divide and Conquer strategy can be viewed as one which has three steps. The first step is called **Divide** which is nothing but dividing the given problems into smaller sub problems which are identical to the original problem and also these sub problems are of the same size. The second step is called **Conquer** wherein we solve these sub problems recursively. The third step is called **Combine** wherein we combine the solutions of the sub problems to get the solution for the original problem.

Control Abstraction for Divide and Conquer Algorithms - General Method

```
Algorithm DandC(P)
{
    if Small(P) then return
        S(P);
    else
    {
        Divide P into smaller instances P1,P2,.....,Pk, k≥1;
        Apply DandC to each of these sub-problems;
        Return Combine(DandC(P1),DandC(P2)...,DandC(Pk)),
    }
}
```

Binary Search

- Binary Search takes a sorted array as the input
- It works by comparing the target (search key) with the middle element of the array and terminates if it equals, else it divides the array into two sub arrays and continues the search in left (right) sub array if the target is less (greater) than the middle element of the array.

Reducing the problem size by half is part of the **Divide** step in Binary Search and searching in this reduced problem space is part of the **Conquer** step in Binary Search. There is no **Combine** step in Binary Search.

```
With Divide and Conquer (recursion)
Algorithm BinSrch(a,i,l,x)
       // Given an array a[I:1] of elements in non-decreasing order, 1 \le i \le l,
      // determine whether x is //present and if so, return j such that x = a[j]; else return 0.
       if (l=i) then
             // if Small(P)
          if (x=a(i)) then
           return i;
         else
           return 0;
       else
       { // Reduce P into a smaller subproblem.
           mid := [(i + 1)/2];
           if (x=a[mid]) then
              return mid;
           else if (x<a[mid]) then
                 return BinSrch (a,i, mid -1,x);
                 return BinSrch (a, mid +1,1,x);
       }
```

Theorem Algorithm BinSearch(a,n,x) works correctly.

Proof: We assume that all statements work as expected and that comparisons such as x>a[mid] are appropriately carried out.

Initially low = 1, high = n, $n \ge 0$, and $a[1] \le a[2] \le ... \le a[n]$.

If n = 0, the while loop is not entered and 0 is returned.

Otherwise we observe that each time through the loop the possible elements to be checked for equality with x are a [low], a[low + 1]..., ..., a[mid],..., a[high).

If x = a[mid], then the algorithm terminates successfully.

Otherwise the range is narrowed by either increasing low to mid + 1 or decreasing high to mid - 1. Clearly this narrowing of the range does not affect the outcome of the search.

If low becomes greater than high, then x is not present and hence the loop is exited.

Performance of Binary Search

Theorem:-If n is in the range $[2^{k-1}, 2^k)$, then BinSearch makes at most k element comparisons for a successful search and either k-1 or k comparisons for an unsuccessful search. (In other words the time for a successful search is 0 (log n) and for an unsuccessful search is (log n).

Proof: Consider the binary decision tree describing the action of BinSearch on n elements. All successful searches end at a circular node whereas all unsuccessful searches end at a square node.

If $2^{k-1} \le n < 2^k$, then all circular nodes are at levels 1, 2,..., k whereas all square nodes are at levels k and k+1 (note that the root is at level 1). The number of comparisons needed to terminate at a circular node on level i is i whereas the number of element comparisons needed to terminate at a square node at level i is only i-1. The theorem follows.

Merge Sort

Merge sort is yet another sorting algorithm which works on the Divide and Conquer design principle.

- Merge sort works by dividing the given array into two sub arrays of equal size
- The sub arrays are sorted independently using recursion
- The sorted sub arrays are then merged to get the solution for the original array.

The **breaking** of the given input array into two sub arrays of equal size is part of the **Divide** step. The recursive calls to sort the sub arrays are part of the **Conquer** step. The merging of the sub arrays to get the solution for the original array is part of the **Combine** step.

The basic operation in Merge sort is comparison and swapping. Merge Sort Algorithm calls it self recursively. Merge Sort divides the array into sub arrays based on the *position* of the elements whereas Quick Sort divides the array into sub arrays based on the value of the elements. Merge Sort requires an auxiliary array to do the *merging* (**Combine step**). The *merging* of two sub arrays, which are already sorted, into an auxiliary array can be done in O(n) where n is the total number of elements in both the sub arrays. This is possible because both the sub arrays are sorted.

Merging in Merge Sort

```
Algorithm Merge (low, mid, high)
   // a[low:high] is a global array containing two sorted subsets in
   // a [low:mid] and in a [mid + 1 :high]. The goal is to merge these
   // two sets into a single set residing in a [low:high]. B[] is an
   // auxiliary global array.
    h:=low; i:=low; j:=mid+1;
    while ((h \le mid) and (j \le high)) do
    {
         if (a[h] \le a[j] then
            b[i] := a[h];h := h+1;
         else
            b[i] := a[j]; j := j+1;
          i := i+1;
     if (h>mid) then
        for k:=j to high do
        \{b[i] : =a[k]; i:=i+1; \}
     else
        for k :=h to mid do
        \{b[i] := a[k]; i := i+1; \}
     for k: =low to high do
         a[k] := b[k];
```

```
Algorithm MergeSort(low, high)

{

// Small(P) is true if there is only one element to sort .

// In this case the list is already sorted.

if (low < high) then

{

//If there are more than one element

//Divide P into subproblems.

mid := [(low + high)/2];

// Solve the subproblems.

MergeSort(low, mid);

MergeSort (mid + 1, high);

// Combine the solutions.

Merge(low, mid, high);

}

}
```

Complexity of Merge Sort is O(n log n) and binary search is O(log n).

This can be proved by repeated substitution in the recurrence relations.

```
Suppose (for simplicity) that n = 2^k for some entire k. as n=2^k k = log2n
Let T(n) the time used to sort n elements. As we can perform separation and merging in linear time, it
takes on time to perform these two steps, for some constant c. So, recurrence relation is: T(n) =
2T(n/2) + cn.
In the same way: T(n/2) = 2T(n/4) + cn/2, so T(n) = 4T(n/4) + 2cn.
Going in this way ...
           T(n) = 2^{m}T(n/2^{m}) + mcn, and
           T(n) = 2^k T(n/2^k) + kcn = nT(1) + cnlog_2 n = O(n log n).
Binary Search:
Let T(n) the time used to search n elements. As we need to search only one of the halves, the
Recurrence relation is : T(n) = T(n/2) + c
In the same way: T(n/2) = T(n/4) + c, so
                                             T(n) = T(n/4) + 2c.
Going in this way ...
           T(n) = T(n/2^m) + mc, and
           T(n) = T(n/2^k) + kc = T(1) + kc = kc + 1 = O(\log n).
```

QuickSort:

Quick sort is one of the most powerful sorting algorithms. It works on the Divide and Conquer design principle. Quick sort works by finding an element, called the **pivot**, in the given input array and **partitions** the array into three sub arrays such that the left sub array contains all elements which are less than or equal to the pivot. The middle sub array contains the pivot. The right sub array contains all elements which are greater than the pivot. Now, the two sub arrays, namely the left sub array and the right sub array are sorted recursively.

The **partitioning** of the given input array is part of the **Divide** step. The recursive calls to sort the sub arrays are part of the **Conquer** step. Since the sorted sub arrays are already in the right place there is no **Combine** step for the Quick sort.

```
    Algorithm QuickSort (p,q)
    // Sorts the elements a[p],..., a[q] which reside in the global
    // array a[1;n] into ascending order; a[n+1] is considered to
    // be defined and must be ≥ all the elements in a[1:n]
    {
    if (p < q) then // if there are more than one element</li>
    {
```

```
8.
            // divide P into two sub problems.
9.
               j := Partition (a,p,q+1);
10.
                   // j is the position of the partitioning element.
             // Solve the subproblems.
11.
12.
               QuickSort (p,j-1),
13.
               QuickSort (j + 1,q)
14.
             // there is no need for combining solutions.
15.
         }
16.
      }
```

Algorithm for Sorting by partitioning

```
1.
      Algorithm Partition (a,m,p)
2.
      //Within a[m],a[m+1],....a[p-1] the elements are
3.
      //rearranged in such a manner that if initially t = a[m],
4.
      // then after completion a[q] = t for some q between m
5.
      // and p-1, a[k] \le t for m \le k < q, and a[k] \ge t
6.
      // for q< k<p. q is returned. Set a[p] = \infty.
7.
8.
          v := a[m], I := m; j := p;
9.
           repeat
10.
           {
11.
              repeat
12.
                       i := i+1;
13.
               until (a[i]≥v);
14.
              repeat
15.
                j := j - 1;
              until (a[j] \le v);
16.
17.
              if (I < i) then interchange (a,I,j);
18.
            } until (l \ge j);
19.
            a[m] := a[j]; a[j] := v; return j;
20.
      }
      Algorithm Interchange ( a , i, j)
1.
2.
      //Exchange a[i] with a [j]
3.
      {
4.
           p := a[i];
5.
           a[i] := a[j]; a[j] : p;
6.
      }
```

Algorithm Partition the array a[m : p-1] about a [m]

(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	i	(p)

STRASSEN'S MATRIX MULTIPLICATION

Let A and B be two n X n matrices. The product matrix C = AB is also an n X n matrix whose i,j th element is formed by taking the elements in the i th row of A and the j th column of B and multiplying them to get

$$\begin{array}{l} C(i,j) = \sum\limits_{1 \leq k \leq n} A(i,\,k) \; B(k,\,j) \end{array}$$

for all i and j between 1 and n. To compute C (i,j) using this formula, we need n multiplication. As the matrix C has n^2 elements, the time for the resulting matrix multiplication algorithm, which we refer to as the conventional method is \emptyset (n^3).

$$\left[\begin{array}{c} A_{1,1} \ A_{1,2} \\ A_{2,1} \ A_{2,2} \end{array} \right] \left[\begin{array}{c} B_{1,1} \ B_{1,2} \\ B_{2,1} \ B_{2,2} \end{array} \right] \ = \ \left[\begin{array}{c} C_{1,1} \ C_{1,2} \\ C_{2,1} \ C_{2,2} \end{array} \right]$$

then

$$\begin{array}{lll} C_{11} &=& A_{11}\,B_{11} + A_{12}\,B_{21} \\ C_{12} &=& A_{11}\,B_{12} + A_{12}\,B_{22} \\ C_{21} &=& A_{21}\,B_{11} + A_{22}\,B_{21} \\ C_{22} &=& A_{21}\,B_{12} + A_{22}\,B_{22} \end{array}$$

Strassen showed that 2x2 matrix multiplications can be accomplished in 7 multiplication and 18 additions or subtractions. This reduce can be done by Divide and Conquer Approach. Divide the input data S in two or more disjoint subsets S1, S2. Solve the sub-problems recursively. Combine the solutions for S1, S2, ..., into a solution for S. The base case for the recursion are sub-problems of constant size. Analysis can be done using recurrence equations. Divide matrices in sub-matrices and recursively multiply sub-matrices.

This method involves first computing the seven n/2 X n/2 matrices as

$$\begin{split} P &= \ (A_{11} + A_{22}) \ (B_{11} + B_{22}) \\ Q &= (A_{21} + A_{22}) \ B_{11} \\ R &= \ A_{11} \ (B_{12} - B_{22}) \\ S &= \ A_{22} \ (B_{21} - B_{11}) \\ T &= (A_{11} + A_{12}) \ B_{22} \\ U &= (A_{21} - A_{11}) (B_{11} + B_{12}) \\ V &= (A_{12} - A_{22}) (B_{21} + B_{22}) \end{split}$$

Then C_{ij}'s are computed as

$$\begin{split} C_{11} &= P {+} S - T + V \\ C_{12} &= R {+} T \\ C_{21} &= Q {+} S \\ C_{22} &= P {+} R - Q + U \end{split}$$

The resulting recurrence relation for T(n) is

$$T(n) = \begin{cases} b & n \le 2 \\ 7T(n/2) + an^2 & n > 2 \end{cases}$$

Where a and b are constants. Working with this formula, we get

$$\begin{split} T(n) &= an^2[1 + 7/4 + (7/4)^2 + \ldots + (7/4)^{k-1}] + 7^k T(1) \\ &\leq cn^2 \left(7/4\right)^{\log_2 n} + 7^{\log_2 n}, \text{ c a constant} \\ &= cn^{\log_2 4} + \log_2 7, \log_2 4 + n \log_2 7 \\ &= 0 \left(n^{\log_2 7}\right) \approx 0(n^{2.81}) \end{split}$$

Greedy Algorithms

Greedy algorithms – overview

Greedy design technique is primarily used in Optimization problems.

Optimization problems are problems where in we would like to find the best of all possible solutions. In other words, we need to find the solution which has the optimal (maximum or minimum) value satisfying the given constraints.

The Greedy approach helps in constructing a solution for a problem through a sequence of steps where each step is considered to be a partial solution. This partial solution is extended progressively to get the complete solution.

In the greedy approach each step chosen has to satisfy the constraints given in the problem. Each step is chosen such that it is the best alternative among all feasible choices that are available. The choice of a step once made cannot be changed in subsequent steps.

Change making example:

Suppose, we want to make change for an amount 'A' using fewest no of currency notes. Assume the available denominations are Rs 1, 2, 5, 10, 20, 50, 100, 500, and 1000.

To make a change for A=Rs 28, with the minimum number of notes, one would first choose a note of denomination Rs 20, 5, 2 and 1.

Denomination table					
for Rs 2	8	for Rs 783		for Rs 3799	
1000 X 0	0	1000 X		1000 X	
500 X 0	0	500 X		500 X	
100 X <mark>0</mark>	0	100 X		100 X	
50 X 0	0	50 X		50 X	
20 X 1	20	20 X		20 X	
10 X 0	0	10 X		10 X	
5 X 1	5	5 X		5 X	
2 X 1	2	2 X		2 X	
1 X 1	1	1 X		1 X	
Total	28	Total		Total	

Greedy Algorithm-General method

In Greedy method the problems have 'n' inputs called as <u>candidate set</u>, from which a subset is selected to form a solution for the given problem. Any subset that satisfies the given <u>constraints</u> is called a <u>feasible solution</u>. We need to find a feasible solution that maximizes or minimizes an <u>objective function</u> and such solution is called an <u>optimal solution</u>.

```
<u>In the above ex</u> Currency notes denomination set { 1000 ....1000 ,500....500, 100....100, 50....50, 20....20,10...10,5...5,2...2,1...1} is candidate set.
```

<u>In the above ex</u> Constraint is our solution make the exact target amount of cash. Hence, any feasible solution i.e. sum of selected notes should be equal to target amount.

<u>In the above ex</u> Objective function is our solution should consist of the fewest number of currency notes. Hence, any optimal solution which is one of the feasible solutions that optimizes the objective function. There can be more than one optimal solution.

Control Abstraction for Greedy General Method

```
Algorithm Greedy (a, n)
// a [1 ..n] contains the n inputs
{
    solution :=ø;
    for i := 1 to n do
        {
                 x := Select (a);
                 if Feasible (solution, x) then solution := Union ( solution, x);
        }
    return solution;
}
```

Greedy method consists of 3 functions (steps).

- 1) Select: it selects an input from array a[] (candidate set) and puts in the variable x.
- 2) <u>Feasible:</u> it is a Boolean function which checks whether the selected input meets the constraints or not.
- 3) <u>Union</u>: if the selected input i.e. 'x' makes the solution feasible, then x is included in the solution and objective function get updated.

Characteristics of Greedy:

- 1) These algorithms are simple and straightforward and easy to implement.
- 2) They take decisions on the basis of information at hand without worrying about the effect these decisions may have in the future.
- 3) They work in stages and never reconsider any decision.

Greedy Algorithms Applications

Knapsack problem:

A thief robbing a store finds n items, the items each worth v_i rupees and weights w_i grams, where v_i and w_i are positive numbers. He wants to take as valuable load as possible but he can carry at most w grams in his knapsack(bag). Which item should he take?

They are two types of knapsack problem.

- 1) 0-1 knapsack problem: Here the items may not be broken into smaller pieces, so thief may decide either to take an item or to leave to it(binary choice). It cannot be efficiently solved by greedy algorithm
- 2) Fractional (General) Knapsack problem: Here thief can take the fraction of items, meaning that the items can be broken into smaller pieces so that thief may be able to carry a fraction x_i of item i. This can be solved easily by greedy.

If a fraction x_i , $0 \le x_i \le 1$, of objects i is placed into the knapsack, then a profit of $p_i x_i$ is earned. The objective is to obtain a filling of the knapsack that maximizes the total profit earned. Since the knapsack capacity is m, we require the total weight of all chosen objects to be at most m.

Formally the problem can be stated as

$$\begin{aligned} & \text{Maximize } \sum P_i \, x_i \, & & & & & & & & & & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... & ... &$$

The profit and weights are positive numbers. A feasible solution is any set $(x_1,x_2,....x_n)$ satisfying (2) and (3). An optimal solution is feasible solution for which (1) is maximized.

Eg. consider the following instance of the knapsack problem.

$$n=3$$
, $m=20$, $(P_1, P_2, P_3) = (25, 24, 15) & $(w_1, w_2, w_3) = (18, 15, 10)$$

Note that knapsack problem calls for select a subset of the objects hence fits the subset paradigm.

1) We can try to fill the knapsack by including the object with largest profit(greedy approach to the profit) .If an object under consideration does not fit, then a fraction of it is included to fit the knapsack. Object 1 has the largest profit value. P_1 =25. So it is placed into the knapsack first. Then x_1 =1 and a profit of 25 is earned. Only 2 units of knapsack capacity are left. Objects 2 has the next largest profit P_2 =24. But W_2 =15 & it does not fit into the knapsack. Using x_2 =2/15 fills the knapsack exactly with the part of the object 2.

The method used to obtain this solution is termed a greedy method at each step, we chose to introduce that object which would increase the objective function value the most.

$$(x1, x2, x3)$$
 $\sum wi xi$ $\sum pi xi$ $(1, 2/15, 0)$ 20 28.2

This is not an optimal solution.

2) We apply greedy approach by choosing value per unit weight is as high as possible

Item(n)	Value(p1,p2,p3)	Weight(w1,w2,w3)	Val/weight
1	25	18	1.388
2	24	15	1.6
3	15	10	1.5

Here $\mathbf{p_2/w_2} > \mathbf{p_3/w_3} > \mathbf{p_1/w_1}$. Now the items are arranged into non increasing order of p_i/w_i . Second item is the most valuable item. We chose item 2 first. Item 3 is second most valuable item. But we cannot choose the entire item3 as the weight of item 3 exceeds the capacity of knapsack. We can take ½ of the third item. Therefore the solution is $x_1 = 0$, $x_2 = 1$, $x_3 = \frac{1}{2}$ and maximum profit is $\sum p_i x_i = 0*25 + 1*24 + \frac{1}{2}*15 = 31.5$

(x_1, x_2, x_3)	$\sum w_i x_i$	$\sum p_i x_i$
(1, 2/15, 0)	20	28.2
(0, 2/3, 1)	20	31
(0, 1, 1/2)	20	31.5

If the items are already arranged in non increasing order of pi/wi, then the function greedy knapsack obtains solution corresponding to this strategy.

Analysis of Greedy Knapsack

- If the items are already sorted into decreasing order of vi/wi, then time complexity is O(n)
- Therefore Time complexity including sort is **O**(**n** log **n**)

Job Sequencing with deadlines:

We are given a set of n jobs. Associated with job i is an integer deadline $d_i \geq 0$ and a profit $P_i \geq 0$. For any job i profit P_i is earned iff the job is completed by its deadline. To complete a job, one has to process job on a machine for one unit of time. Only one machine is available for processing jobs. A feasible solution for this problem is a subset J of jobs such that each job in this subset can be completed by its deadline. The value of a feasible solution J is the sum of the profits of the jobs in J, or $\sum P_i$. An optimal solution is a feasible solution with maximum value. Here the problem involves the identification of a subset, it fits the subset paradigm.

Eg; Let n=4. $(P_1,P_2,P_3,P_4) = (100,10,15,27)$ and $(d_1,d_2,d_3,d_4)=(2,1,2,1)$. $d_1 = 2$ means first job should be completed by first 2 units of time. $d_2 = 1$ means second job should be completed by first 1 unit of time. The feasible solutions and their values are

	Feasible solution	processing sequence	value
1.	(1,2)	2,1	110
2.	(1,3)	1,3 or 3,1	115
3.	(1,4)	4,1	127
4.	(2,3)	2, 3	25
5.	(3,4)	4,3	42
6.	(1)	1	100
7.	(2)	2	10
8.	(3)	3	15
9.	(4)	4	27

Solution 3 is optimal. In this solution job 1 & 4 are produced and the value is 127. These jobs must be processed in the order job 4 followed by job 1. Thus the processing of job 4 begins at time zero & that of job 1 is completed at time2

We can choose the objective function $\sum P_i$, i ϵ J as one optimization measure. Using this measure, the next job to include is the one that increases $\sum P_i$, i ϵ J the most, subject to the constraint that the resulting J is a feasible solution. This requires us to consider jobs in decreasing order of P_i 's.

From the above example we begin with $J=\emptyset$ and $\sum P_i=0$, i ϵ J. Jobs 1 is added to J as it has the largest profit and $J=\{1\}$ is a feasible solution. Next job 4 is considered. The solution $J=\{1,4\}$ is also feasible. Next job 3 is considered and discarded as $J=\{1,3,4\}$ is not feasible. Hence we are left with the solution. $J=\{1,4\}$ with value 127. This is the optimal solution for the problem instance.

High level description of Greedy Algorithm for Job Sequencing with deadlines:

```
Algorithm GreedyJob (d, J,n)

{

// job 1, job 2, job 3,.... job n are in the non-increasing order of their profits

J := { job1 };

for i := 2 to n do

{

if all jobs in J and job i together can be completed by their deadlines then

add job i to J;

}
```

Detailed Greedy Algorithm for Job Sequencing with deadlines:

```
Algorithm JS(d, j, s)
  //d[i] \ge 1, 1 \le i \le n are the dead lines, n \ge 1. The jobs
  //are ordered such that P[1] \ge p[2] \ge ... \ge p[n]. J[i]
  //is the i th job in the optimal solution , 1 \le i \le k.
  //Also, at termination d[J[i]] \le d[J[i+1]], 1 \le i < k.
   d[0] := J[0] := 0; //Initialize.
   J[1] := 1;// Include job 1.
   K:=1:
   for i = 2 to n do
        // Consider jobs in non-increasing order of p[i]: Find
        // Position for i and check feasibility of insertion.
        r := k:
        While (d[J[r]]>r]]>d[i]) and (d[J[r]]\neq r) do
                 r := r - 1;
        if ((d[J[r]] \le d[i]) and (d[i] > r)) then
        {
                 // Insert i into J [ ].
                 for q := k \text{ to } (r+1) \text{ step -1 do}
                         J[q+1] := J[q];
                 J[r+1] := i; k := k+1;
        }
    return k;
}
```

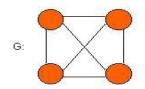

Minimum Spanning Tree

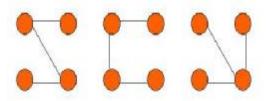

A tree is defined to be an undirected, acyclic and connected graph (or more simply, a graph in which there is only one path connecting each pair of vertices).

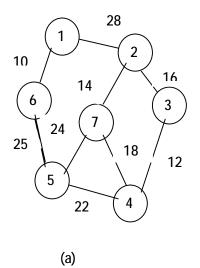

Assume there is an undirected, connected graph G. A spanning tree is a sub-graph of G, is a tree, and contains all the vertices of G. A minimum spanning tree is a spanning tree, but has weights or lengths associated with the edges, and the total weight of the tree (the sum of the weights of its edges) is at a minimum

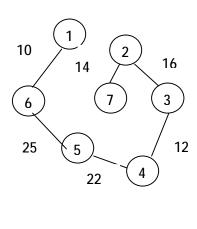

Application of MST

- 1) Practical application of a MST would be in the design of a network. For instance, a group of individuals, who are separated by varying distances, wish to be connected together in a telephone network. MST can be used to determine the least costly <u>paths</u> with no <u>cycles</u> in this network, thereby connecting everyone at a minimum cost.
- 2) Another useful application of MST would be finding airline routes MST can be applied to optimize airline routes by finding the least costly paths with no cycles

(b)

Prim's Algorithm (DJP algorithm, the Jarník algorithm, or the Prim-Jarník algorithm).

Prim's algorithm finds a minimum spanning tree for a connected weighted graph. This means it finds a subset of the edges that forms a tree that includes every vertex, where the total weight of all the edges in the tree is minimized.

<u>Steps</u>

- **Ø** Builds the tree edge by edge
- **Ø** Next edge to be selected is one that result in a minimum increase in the sum of costs of the edges so far included
- **Ø** Always verify that resultant is a tree

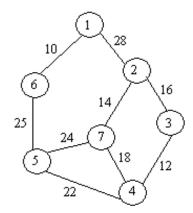

Algorithm Prim(E,cost,n,t)

```
//E is the set of edges in G.cost [1:n, 1:n] is the cost
//adjacency matrix of an n vertex graph such that cost[i, j]is
//either a positive real number or of if no edges(i, i) exists.
//A minimum spanning tree is computed and stored as set of
//edges in the array t[1:n-1,1:2], (t[i,1],t[i,2]) is an edge in
//the minimum—cost spanning tree. The final cost is returned.
       Let (k,l) be an edge of minimum cost in E;
       mincost := cost[k,l];
       t[1,1] := k; t[1,2] := l;
       for i := 1 to n do //Initialize near.
               if (cost[i, l] < cost[i, k]) then
                       near[i] := l;
               else
                        near[i]:=k;
       near[k] := near[1] := 0;
       for i := 2 to n-1 do
       \{ // \text{ Find } n - 2 \text{ additional edges for t. } \}
               Let j be an index such that near [j] \neq 0 and
               cost [j,near[j]] is minimum;
               t[i,1]:=j; t[i,2]:=near[j];
               mincost := mincost + cost[j,near [j]];
               near[i]:=0;
               for k:=1 to n do // Update near[]
                       if((near[k]\neq0) and (cost[k,near[k]] > cost[k,j]))then
                               near[k]:=j;
       return mincost:
}
```

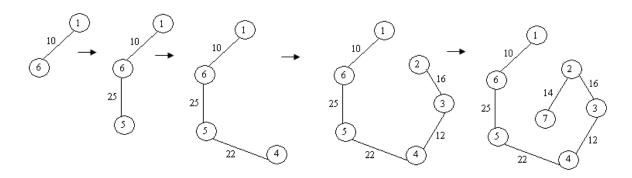

Time complexity of the above algorithm is $O(n^2)$.

Ex:

Consider the connected graph given below

Minimum spanning tree using Prim's algorithm can be formed as follows.

Kruskal's Algorithm

Kruskal's algorithm is another algorithm that finds a minimum spanning tree for a connected weighted graph. If the graph is not connected, then it finds a *minimum spanning forest* (a minimum spanning tree for each connected component).

Kruskal's Algorithm builds the MST in forest. Initially, each vertex is in its own tree in forest. Then, algorithm considers each edge in turn, order by increasing weight. If an edge (u, v) connects two different trees, then (u, v) is added to the set of edges of the MST, and two trees connected by an edge (u, v) are merged into a single tree on the other hand, if an edge (u, v) connects two vertices in the same tree, then edge (u, v) is discarded. The resultant may not be a tree in all stages. But can be completed into a tree at the end.

```
t = EMPTY;
while ((t has fewer than n-1 edges) && (E != EMPTY))
{
      choose an edge(v, w) from E of lowest cost;
      delete (v, w) from E;
      if (v, w) does not create a cycle in t
            add (v, w) to t;
      else
            discard (v, w);
}
```

To check whether there exist a cycle, place all vertices in the same connected component of t into a set. Then two vertices v and w are connected in t then they are in the same set.

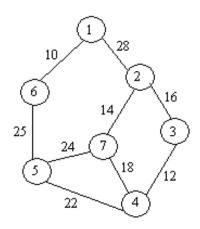

Kruskal's Algorithm

```
Float kruskal (int E[][], float cost[][], int n, int t[][2])
   int parent[w];
   consider heap out of edge cost;
   for (i=1; i<=n; i++)
           parent[i] = -1;
                                  //Each vertex in different set
   i=0;
    mincost = 0;
    while((i<n-1) && (heap not empty))
    {
           Delete a minimum cost edge (u,v) from the heap and re heapify;
           j = Find(u);
                          k = Find(v);
                                                 // Find the set
           if (j != k)
           {
                   i++;
                   t[i][1] = u;
                   t[i][2] = v;
                   mincost += cost[u][v];
                   Union(j, k);
           if (i != n-1)
                   printf("No spanning tree \n");
           else
                   return(mincost);
    }
}
```

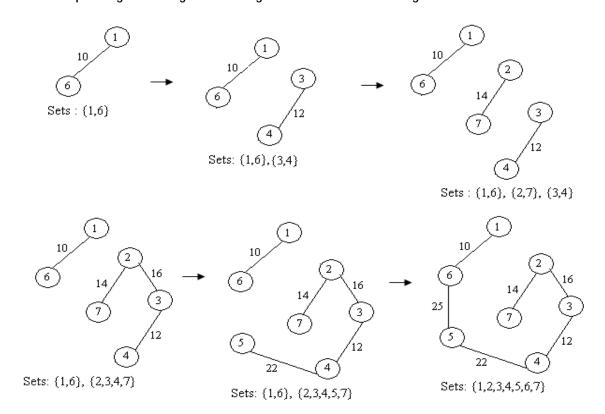

Time complexity of the above algorithm is O(n log n)

Example:

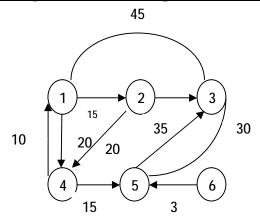

Consider the connected graph given below:

Minimum spanning tree using Kruskal's algorithm can be formed as given below.

Greedy Algorithm for Single-source shortest paths to all other vertices

Pat	h	Length		
1)	1.4	10		
2)	1.4.5	25		
3)	1.4.5.2	45		
4)	1.3	45		

(b) Shortest path from 1

Greedy algorithm to generate shortest paths

```
Algorithm Shortest paths (v, cost ,dist, n)
// dist[j]. 1 \le j \le n, is set to the length of the shortest
// path from vertex v to vertex j in a digraph G with n
// vertices, dist[v]is set to zero. G is represented by its
// cost adjacency matrix cost[1:n,1;n]
    for i:=1 to n do
    { // Initialize S.
        S[i] := false; dist[i] := cost[v,i];
    S[v] := true; dist[v] := 0.0; //put v in S.
    for num := 2 to n do
      // Determine n - 1 paths from v.
        Choose u from among those vertices not
        in S such that dist[u] is minimum;
        S[n] := true; //put u in S.
         for (each w adjacent to u with S[w] = false) do
              // Update distances.
               if(dist[w] > dist[u] + cost[u,w])) then
                  dist[w] := dist[u] + cost[u, w];
                                                                                     Boston
                                                                                       5
}
                           San Francisco
                                                               Chicago
                                                                              1500
                                                                                          250
                                                                          1000
                                                                                          New York
                                          800
                                2
                                                 3
                          300
                                                                           1400
                                                                                      Ø00
                                              Denver
                                        1000
                                                1700
                           Los Angeles
                                                                               Miami
                                                          New orleans
                 1
                        2
                                                            7
                                                                    8
                              3
                                            5
                                                    6
          1.
               0
          2.
               300
                      0
          3.
